

3. Project Design Phase

Objective

To design the logical workflow and access control structure for restricting record access based on a specific field value using a script-controlled ACL.

Activities Performed

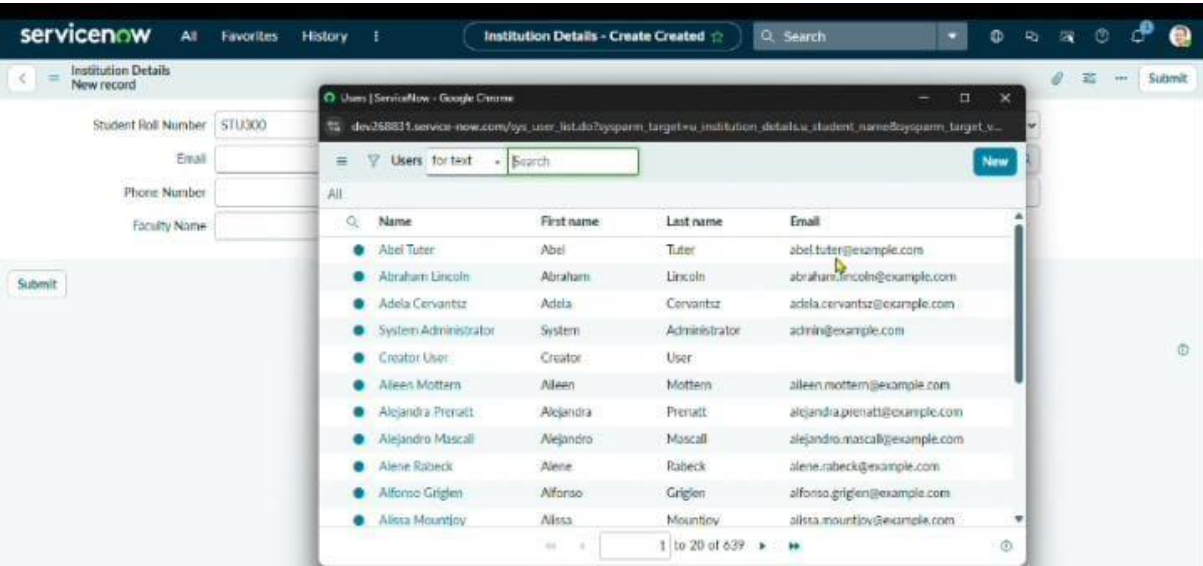

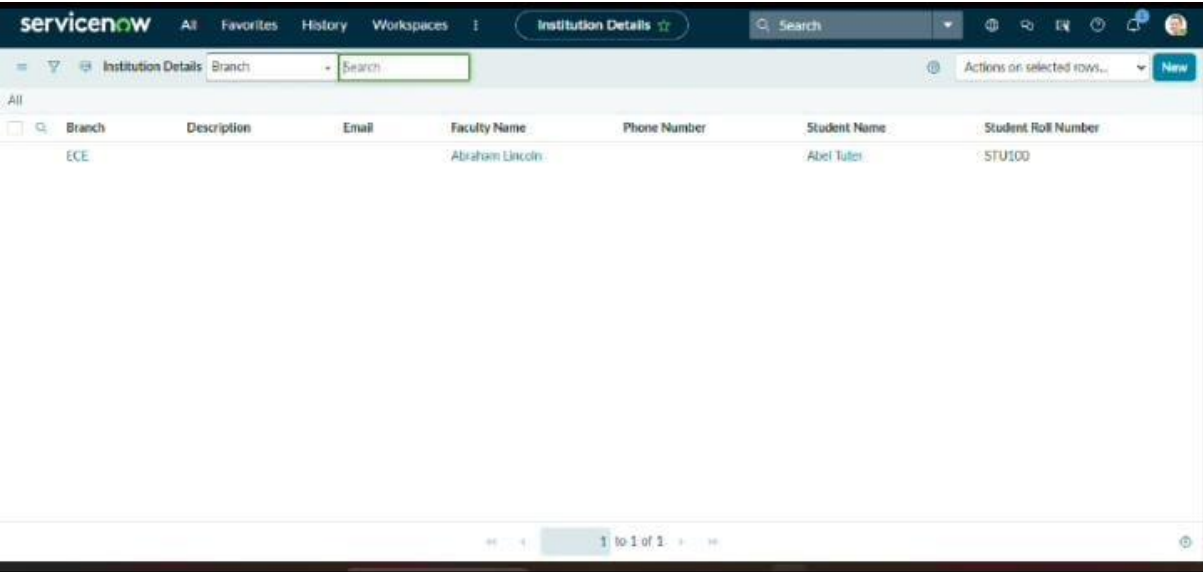

- Design the ACL that controls access to the required records.
- Identify the field value that determines whether access should be granted or denied.
- Create a script condition to check the field value of the record.
- Define the access rules for authorized and unauthorized records.
- Configure the ACL to allow access when the required condition is satisfied.
- Define the action for denying access when the field value does not meet the condition.
- Test the ACL with different field values to verify record-level security.

Expected / Produced Output

High-level access control design:

User Request → ACL Trigger → Field Value Check → Condition Evaluation → Allow Access / Deny Access → Record Display
